

There is a special kind of dread that comes from hearing water where water has no business being. Behind a wall. Under a slab. Dripping into a light fixture, which is always a memorable collaboration between plumbing and electrical anxiety. If your house is old enough to have “character,” there is a fair chance some of that character is hiding in the pipes.

Plumbing repiping is one of those projects homeowners tend to postpone until the house starts sending handwritten threats. A pinhole leak here. Rusty water there. A shower that turns cold when someone looks at the dishwasher. At first, you call for plumbing leak repair and patch the obvious problem. Fair enough. No one wakes up on a Tuesday excited to replace every water line in the house. But eventually the question changes from “Can we fix this leak?” to “How many more leaks are waiting behind the drywall?”

That is when pipe material matters. Copper, PEX, CPVC, and a handful of modern alternatives all have their place. None are magic. All can fail when installed poorly. The right choice depends on your water chemistry, climate, budget, local code, the layout of the home, and whether your installer actually knows the difference between “tight enough” and “I have created a future insurance claim.”

Let’s walk through the real options, with the kind of practical detail you only appreciate after crawling through attic insulation in August or opening a wall and finding three generations of pipe repairs stacked like bad decisions.

When repiping stops being optional

One leak does not always mean a whole-home repipe. Pipes, like knees and pickup trucks, can make disturbing noises for years before they truly give up. But certain patterns tell a different story.

If you have galvanized steel water lines, replacement is usually a matter of when, not if. Galvanized pipe corrodes from the inside. The outside can look merely old while the inside has narrowed to the diameter of a drinking straw. That is why older homes sometimes have water pressure that feels less like a shower and more like a polite suggestion.

Polybutylene, common in some homes built from the late 1970s into the mid-1990s, is another material that often leads to full replacement. It has a history of failures at fittings and along pipe runs, especially where chlorine and pressure fluctuations do their slow, sneaky work. If you have gray plastic piping stamped with PB markings, get it evaluated by a licensed Plumber before it auditions for a disaster movie.

Copper can also reach the end of its useful life. People tend to think of copper as permanent, like cast iron pans or family grudges, but water chemistry matters. Aggressive water, poor installation, excessive velocity, bad grounding practices, and certain ***air conditioning system tune-up*** soil conditions can cause pinhole leaks. One pinhole leak might be bad luck. Several within a few years usually means the system is trying to tell you something in Morse code.

A repipe becomes especially sensible when leaks appear in finished walls, when pressure is poor throughout the home, when water is discolored after sitting, when old repairs are scattered everywhere, or when you are already remodeling kitchens and bathrooms. If the walls are open, that is the house giving you a coupon.

Copper: the classic with a few expensive habits

Copper has been the premium residential water pipe material for decades, and for good reason. It is durable, heat tolerant, rigid, familiar to inspectors, and tidy when installed by someone who takes pride in straight lines. A

properly installed copper system can last 50 years or more under favorable conditions. It handles high temperatures well, which makes it especially popular near water heaters, boilers, and mechanical rooms.

Copper also resists UV damage better than many plastics and does not sag when strapped correctly. It has a pleasing permanence to it. Homeowners like seeing copper in a mechanical room because it looks like someone competent has been there. Whether that is true depends on the solder joints, but optimism is part of homeownership.

The downside is cost. Copper pipe prices fluctuate with metal markets, and labor takes longer than many plastic systems. Installing copper requires cutting, cleaning, fluxing, soldering or using approved press fittings, and protecting nearby framing from heat when soldering. A good technician makes it look simple. A careless one can scorch studs, leave weak joints, or create little green crusty monuments to impatience.

Copper is also vulnerable to certain water conditions. Low pH, high dissolved oxygen, high chloride levels, excessive water velocity, and improper electrical grounding can contribute to corrosion. I have seen homes where copper lasted sixty years without complaint and others where pinhole leaks showed up in under twenty. The pipe did not change its personality. The water did.

If your area has known aggressive water, copper may still be viable, but it deserves a water test and a frank discussion. Sometimes a water softener installation or water treatment system protects fixtures and appliances, but softening alone does not solve every corrosion issue. In fact, water treatment should be designed around actual test results, not around whichever gadget has the shiniest brochure.

Copper is also less forgiving during freeze events. Water expands when it freezes, and copper can split. PEX tends to tolerate freezing better, though “better” does not mean “invincible.” Any pipe can fail if frozen hard enough.

PEX: flexible, fast, and not just the budget option anymore

PEX, short for cross-linked polyethylene, has become the dominant choice for many residential repiping projects. It is flexible, efficient to install, and excellent for retrofits. In older houses where pipes snake through tight chases, under floors, across attics, and around framing that appears to have been designed during a lunch break, PEX is often the difference between a manageable project and a drywall demolition festival.

PEX comes in several types, commonly PEX-A, PEX-B, and PEX-C. Without turning this into a chemistry lecture, the differences involve manufacturing method, flexibility, kink repair, fittings, and cost. PEX-A is typically the most flexible and is often used with expansion fittings. PEX-B is commonly used with crimp or clamp fittings and is widely available. PEX-C is less common in many repipe markets. All can work when properly rated, installed, and protected.

PEX has real advantages. It reduces the number of fittings because long flexible runs can bend around obstacles. Fewer fittings usually means fewer potential leak points. It is quieter than copper, resists scale buildup better than galvanized steel, and does not pit the way copper can under certain water chemistry conditions. It also installs faster, which can reduce labor costs and disruption.

Still, PEX is not a license to abandon craftsmanship. It must be supported correctly. It must be protected from UV light. It should not be installed too close to recessed lights, flues, or other heat sources. Rodents can chew it, because apparently some animals look at plumbing and think “snack infrastructure.” It also expands and contracts with temperature changes, so installers need to account for movement. A tight, unsupported, rubbing PEX line can eventually make noise or wear.

One concern homeowners ask about is taste or odor. New PEX can sometimes contribute a temporary plastic taste, depending on the product, water chemistry, and usage patterns. Approved potable-water PEX must meet

standards, but if you are particularly sensitive, ask about pipe brands, certifications, and flushing procedures. Most issues fade after proper flushing and regular use.

PEX is often installed in a branch-and-tee layout, similar to copper, or as a home-run manifold system. A manifold setup sends individual lines from a central distribution point to each fixture. It uses more pipe but can reduce hidden fittings and allow fixture shutoffs in one location. It is a beautiful thing when the upstairs toilet misbehaves at 11 p.m. And you can isolate it without shutting down the whole house. Small luxuries matter.

CPVC: the plastic veteran with strong opinions

CPVC, chlorinated polyvinyl chloride, has been used in residential water distribution for decades. It is rigid, relatively inexpensive, and easy to cut and solvent-weld. In some regions, it is still common. In others, plumbers approach old CPVC the way one approaches a sleeping raccoon, cautiously and with an exit plan.

The issue is not that CPVC cannot work. It can. Properly installed CPVC in compatible conditions may provide many years of service. It handles hot and cold potable water and does not corrode like metal pipe. It also requires basic tools and is familiar to many inspectors.

The trouble comes with aging, brittleness, installation quality, and compatibility. Older CPVC can become fragile, especially in hot attics or where it has been exposed to stress, certain chemicals, or repeated thermal cycling. I have seen a simple shutoff valve replacement turn into a larger repair because the pipe cracked several inches away from the work. Nobody enjoys explaining that the pipe broke because it was already brittle, not because the wrench was haunted.

CPVC also depends on proper solvent cement technique. The pipe and fitting must be cut square, cleaned, primed if required, cemented correctly, fully inserted, and allowed to cure. Too little cement creates weak joints. Too much can soften material or create restrictions. Rushing cure times before pressurizing the system is another classic way to create leaks with confidence.

For whole-home repiping, CPVC may still be a budget option where code allows and local conditions favor it. But many contractors now recommend PEX or copper instead, especially for retrofits. CPVC can be perfectly acceptable in specific applications, yet it rarely wins the “best all-around modern repipe material” argument unless price is the primary driver.

Other modern pipe materials worth knowing

Residential repiping is usually a copper-versus-PEX conversation, with CPVC stepping in depending on region and budget. But other materials appear in certain homes and applications.

Stainless steel is used in some specialty situations, more often commercially or in high-corrosion environments. It is durable but expensive, and it requires the right fittings and installation practices. For a typical house, it is usually overkill unless there is a specific water chemistry or design reason.

Polypropylene piping, including PP-R systems, is more common in some markets and commercial work than in everyday residential repipes in many parts of the United States. It uses heat-fused joints rather than solder or crimp fittings. When installed correctly, fusion joints are strong and clean. The catch is installer familiarity. A great material in untrained hands is still a problem wearing a nicer hat.

Flexible stainless connectors and corrugated stainless steel tubing have roles in appliance and gas installation service work, but they are not whole-house potable water distribution in the same sense as copper or PEX. Gas

piping, of course, is its own world, with its own codes, sizing rules, bonding requirements, and consequences for improvisation. If someone treats gas pipe like a casual DIY experiment, do not walk away. Jog.

For drain, waste, and vent systems, materials such as PVC, ABS, and cast iron dominate, but that is a different conversation. A water supply repipe does not automatically mean replacing drain lines. However, if your old cast iron drains are cracked, scaling, or repeatedly clogging, you may end up talking about drain cleaning, Rooter service, Hydrojetting, camera inspection, and possibly drain replacement at the same time. Houses love bundling expenses like a cable company.

The real-world comparison homeowners actually need

Pipe material debates can get oddly emotional. Some plumbers swear by copper. Some prefer PEX. Some have opinions so strong they should come with a pressure regulator. The better approach is to match the material to the job.

Material	Strengths	Watch-outs	Best fit
Copper	Long track record, heat resistant, rigid, professional appearance	Higher cost, corrosion risk with certain water, freeze splits	Mechanical rooms, exposed runs, homeowners who want a traditional premium system
PEX	Flexible, fast installation, fewer fittings, good retrofit choice	UV sensitivity, heat clearance, support quality, rodent risk	Whole-home repipes, tight access areas, manifold systems
CPVC	Lower material cost, corrosion resistant, simple tools	Can become brittle, solvent joints require care, regional preference varies	Budget-conscious projects where local experience is strong
Polypropylene	Heat-fused joints, clean system, corrosion resistant	Requires trained installers and specific tools	Select residential or commercial projects with experienced contractors

That table is useful, but it does not show the part that really determines outcome: the installer. A sloppy PEX job can fail early. A thoughtful CPVC job can last. A beautiful copper repipe can still pinhole if the water chemistry is wrong. Pipe material matters, but design and workmanship matter just as much.

What a repipe actually involves

A whole-home repipe is part plumbing, part logistics, part controlled chaos. The first step is evaluation. A contractor should identify the existing pipe material, inspect accessible lines, check water pressure, ask about leak history, review fixture count, and look at the water heater, main shutoff, hose bibbs, and pressure reducing valve if present. If pressure is too high, the new piping may be blamed later for a problem created by poor pressure control. Water pressure over about 80 psi is generally considered too high for many residential systems and may require a pressure reducing valve, depending on local code.

Access planning comes next. Repiping through attics, crawl spaces, basements, garages, closets, and soffits can reduce drywall cuts. Slab homes require extra strategy. Sometimes water lines are abandoned under the slab and rerouted overhead through the attic or walls. That can be smart, but in hot or freezing climates, attic routing needs insulation, heat protection, and careful placement. A pipe in an attic can have a hard life, baking in summer and shivering in winter.

Water service lines deserve separate attention. The pipe from the meter or well to the house may be copper, galvanized, PVC, polyethylene, or something else depending on age and region. Replacing interior piping while ignoring a restricted or leaking service line can leave homeowners disappointed. It is like buying new running shoes and refusing to remove the pebble from your sock.

The water heater area often gets upgraded during a repipe. Shutoff valves, expansion tanks, dielectric unions where appropriate, earthquake straps in seismic regions, drain pans, temperature and pressure relief discharge

piping, and code-compliant venting all matter. If the water heater is old or failing, water heater installation during the repipe may be sensible. If it is fairly new but acting up, water heater repair may be enough. Either way, the new piping should not be connected to a neglected heater setup that looks like it was assembled during a power outage.

Permits and inspections vary by jurisdiction, but many whole-home repipes require them. A reputable contractor should know local rules and not act offended when you ask. Inspectors are not party crashers. They are there to make sure the work meets minimum safety standards, which is a phrase less glamorous than “luxury renovation,” but far more useful when water is involved.

Copper versus PEX in older homes

Older homes are where this decision gets interesting. The walls are often plaster, the framing may be irregular, and previous owners may have left behind plumbing choices that belong in a museum of questionable confidence.

Copper in an older home can be excellent if access is reasonable. In basements with open joists, copper can be run cleanly and securely. It is also a strong choice where piping remains visible, such as in utility rooms. But fishing rigid copper through finished walls is more invasive than pulling flexible PEX. More cuts, more labor, more patching.

PEX shines in retrofits. It can be routed with less destruction and often allows crews to finish faster. A typical whole-home PEX repipe in a modest single-story house might take a couple of days for plumbing work, plus drywall repair and paint afterward. Larger two-story homes, slab foundations, complex fixture layouts, and code upgrades can stretch the timeline. Copper often takes longer and costs more, though local labor markets vary.

There is also the question of noise. Copper expands when hot water flows through it and can tick or ping if holes are tight or supports are poor. PEX can move too, but it tends to be quieter when installed with room for expansion. Water hammer can affect any system and should be handled with proper fastening, pressure control, and hammer arrestors where needed, especially at quick-closing valves on washing machines, dishwashers, and some ice makers.

If the house has knob-and-tube wiring, outdated electrical panels, or ungrounded circuits, a repipe can reveal electrical issues. Water and electricity are neighbors that should maintain boundaries. An Electrician may need to evaluate bonding, grounding, lighting circuits, or fixtures exposed during wall access. If water has leaked into ceiling fixtures, a Lighting contractor or electrician should inspect before anyone casually flips switches like a game show contestant.

Water quality and pipe life

Water chemistry is the quiet villain or hero in many repipe stories. Hard water leaves scale in fixtures and water heaters. Acidic water can attack copper. Chloramine disinfectants, common in many municipal systems, can affect some elastomers and components over time. High chloride levels can be corrosive. Well water may bring iron, manganese, sediment, sulfur odor, low pH, or bacteria concerns.

This is why “Which pipe lasts longest?” is not always the right question. The better question is “Which pipe works best with my water, my house, and my maintenance habits?” Copper may last beautifully in one neighborhood and struggle across town. PEX may avoid corrosion but still need protection from heat and sunlight. Fixtures, valves, appliance connectors, and water heater components each have their own tolerances.

Water softener installation can help with hardness, reducing scale in water heaters, faucets, showerheads, and appliances. It can make soap behave like soap again instead of like a disappointing science project. But softeners add sodium or potassium depending on system type, require maintenance, and should be sized correctly. If corrosion is the issue, treatment may involve neutralizers, filters, or other equipment rather than a standard softener. Testing first saves money and arguments.

A repipe is also a good time to add accessible shutoff valves. Main shutoff valves should operate smoothly. Fixture shutoffs should not crumble when touched. Hose bibbs should be secured and, in freeze-prone areas, frost-protected where appropriate. The best leak is the one you can isolate in ten seconds while still wearing slippers.

Budget, disruption, and the drywall truth

Homeowners often ask for a ballpark cost, and the honest answer is that repiping prices vary widely. A small single-bath home with easy crawlspace access is not the same animal as a two-story slab home with four bathrooms, a recirculation loop, a finished basement, and a dog that judges tradespeople.

Material choice affects cost, but access often affects it more. PEX usually costs less than copper because installation is faster and material is cheaper. Copper can cost significantly more, especially when copper prices are high and the layout is complex. CPVC may be lower still in some regions, though long-term value depends on local conditions and installation quality.

Drywall repair is frequently separate from plumbing. Some plumbing companies include patching, some coordinate it, and others leave clean openings for a drywall contractor. Ask before the work starts. There is a big difference between “we patch and texture everything” and “we leave rectangular memories in every room.”

During the repipe, water may be off for portions of the project. Good crews plan temporary service whenever practical, especially on multi-day jobs. They protect floors, cover furniture, label lines, and clean up. Less careful crews treat your home like a jobsite with a mortgage attached. You can tell a lot from the way a contractor discusses dust control and access panels.

How repiping connects to the rest of the mechanical system

Plumbing does not live alone. It shares walls, ceilings, attics, crawl spaces, and mechanical rooms with heating, cooling, electrical, and sometimes septic components. A good contractor notices these intersections rather than pretending pipes exist in a separate universe.

If a repipe runs through an attic near ductwork, coordination with an Air conditioning contractor or Heating contractor may be useful, especially if ducts need to be moved or sealed. Attic work around refrigerant lines, condensate drains, and air handlers requires care. Nobody wants a new water line rubbing against an air conditioning line until one of them loses the argument.

If you already have an air handler in the attic, this may be a good time to inspect condensate drains and pans. Many ceiling stains blamed on roof leaks or plumbing leaks come from clogged AC drains. Air conditioning maintenance and an air conditioning tune-up can catch those issues before summer turns your ceiling into papier-mâché. If the system is struggling, an Air conditioning repair service can check it while access is available. Air conditioning repair may not be part of repiping, but home systems love to overlap in inconvenient places.

Heating equipment matters too. A Furnace repair service or HVAC technician may need to review venting and clearances if plumbing is routed near furnaces, flues, or combustion air openings. Heat pump installation sometimes changes mechanical room layouts, condensate routing, or water heater decisions, particularly when homeowners move toward hybrid heat pump water heaters. Those units need space, air volume, condensate drainage, and sometimes electrical upgrades.

Homes on septic systems need special awareness during major plumbing work. A repipe itself affects water supply, not wastewater treatment, but fixture upgrades, new water treatment backwash, or changes in household water use can affect septic performance. If drains are slow or gurgling, a Septic system service provider may need to inspect before everyone blames the new pipes. Drain cleaning may solve a branch clog. Rooter service may clear roots temporarily. Hydrojetting may scour a greasy or root-invaded line when appropriate. But a failing drain field is a different beast, and it does not care how nice your new PEX manifold looks.

Signs your contractor knows what they are doing

Choosing pipe material is important. Choosing the person installing it is more important. Good repiping contractors ask questions before offering certainty. They look at the main, not just the pretty parts under the sink. They discuss pressure, water quality, insulation, access, permits, and code upgrades. They explain what will be opened, what will be abandoned, and how the system will be tested.

A solid proposal should identify the pipe material and brand or standard, fitting type, warranty terms, scope of drywall access, fixture connections, valve replacements, water heater tie-ins, permit responsibility, and cleanup expectations. If the proposal just says “repipe house” with a number at the bottom, that is not a contract. That is a fortune cookie with pricing.

Here is a short homeowner checklist worth keeping during estimates:

1. Ask whether the contractor is licensed, insured, and experienced with your chosen pipe material.
2. Confirm whether permits, inspections, drywall repair, and paint are included.
3. Discuss water pressure testing, pressure reducing valves, and expansion tanks.
4. Ask how pipes will be protected from freezing, heat, UV exposure, and abrasion.
5. Get the warranty in writing, including labor and materials.

That **Plumber** is one of the few lists worth having because forgetting any of those items can turn a repipe from “glad we did it” into “why is there a hole behind the bookcase?”

Common mistakes that shorten pipelife

The saddest repipes are the ones done twice. Not because the material failed, but because shortcuts were hidden behind walls until physics filed a complaint.

PEX installed without proper support can sag, rub, or knock. Lines pulled tight through framing can squeak or wear. Pipes placed too close to can lights, furnace flues, water heater vents, or attic heat sources can suffer damage. Copper installed without reaming can create turbulence and erosion at joints. Poor soldering can leave weak spots. CPVC assembled with sloppy solvent cement technique can leak or crack. Any material installed without pressure regulation can be abused by high municipal pressure.

Mixing metals requires care. Dielectric corrosion can occur when dissimilar metals connect improperly in the presence of water. Brass transition fittings, dielectric unions where appropriate, and manufacturer-approved connections matter. So does electrical bonding. Metal water piping has often served as part of grounding and bonding systems. Replacing metal pipe with plastic can interrupt that path. That is not a plumbing footnote. It is a safety issue, and an Electrician should correct bonding when needed.

Another mistake is undersizing. Modern homes often have multiple bathrooms, large tubs, body sprays, irrigation connections, ice makers, pot fillers, and laundry appliances. Repiping is a chance to size trunk lines properly and improve fixture performance. That does not mean every pipe should be oversized. Oversized hot water lines waste water and energy because you wait longer for hot water. Smart sizing balances flow, pressure, and hot water delivery.

Hot water recirculation deserves thought. A recirculation system can reduce wait time at distant fixtures, but it must be designed correctly. Continuous circulation can waste energy and may increase wear on piping and water heaters if temperatures and velocities are not controlled. Timers, aquastats, demand controls, proper check valves, and insulation improve performance. If your master shower is three zip codes from the water heater, recirculation may be worth discussing.

Repair, partial repipe, or full repipe?

Not every home needs the full treatment. Sometimes a single failed section can be replaced. Sometimes only galvanized branches remain while mains have already been upgraded. Sometimes a bathroom remodel justifies repiping that room and tying into existing lines. A good Plumber should tell you when a smaller repair makes sense.

Partial repiping can be practical when the remaining system is in decent shape and accessible. It can also be a trap when old pipe is left in concealed areas and fails soon after new work is completed. The decision depends on pipe age, material, leak history, access, and budget. If three sections of galvanized have failed and the fourth is buried behind tile, pretending the fourth is immortal is not optimism. It is scheduling.

For homeowners planning major renovations, full repiping before finishes go in is usually wise. New cabinets, tile, flooring, and paint make future pipe replacement more painful and expensive. If you are spending serious money on a kitchen or bathroom, old supply lines behind the new work are like wearing socks with holes under a tuxedo. Technically possible. Spiritually wrong.

The best choice for most homes

For many residential repiping projects, PEX offers the best balance of cost, speed, flexibility, and performance. That is why it has become so common. It works especially well in retrofit situations and complex layouts. When

installed with quality fittings, proper support, careful routing, and code-compliant protection, it is a strong modern choice.

Copper remains an excellent material where budget allows, water chemistry supports it, and the homeowner values durability, heat resistance, and rigid installation. It is particularly attractive for exposed mechanical areas and certain high-temperature applications. Some homes use a hybrid approach, with copper near the water heater or exposed utility areas and PEX through the rest of the structure. That can be a very sensible compromise, not a plumbing identity crisis.

CPVC still has a place, but I would be more selective with it for whole-home repiping, especially in hot attics, areas with a history of brittle failures, or homes where future repairs may disturb old piping. If local contractors have deep experience with it and the conditions are right, it can perform. If not, PEX or copper usually makes the stronger case.

The final choice should come after looking at the house, not just reading the label on a pipe. Water chemistry, pressure, access, climate, budget, code, and installer skill all shape the answer.

A repipe is not glamorous, which is exactly why it matters

Nobody invites friends over to admire a new manifold the way they show off countertops. Though, frankly, some manifolds deserve better social lives. Repiping is hidden work. If it is done well, you stop thinking about it. The showers run properly. The rusty water disappears. The mystery stains stop spreading. The main shutoff actually shuts off. The house becomes less dramatic, and less dramatic is a fine goal for plumbing.

The best repipe is the one designed for the home you actually have, not the one on a product brochure. Copper, PEX, CPVC, and newer materials can all succeed in the right setting. They can all disappoint when installed carelessly. Ask better questions, look beyond the cheapest number, and pay attention to the parts nobody sees.

Because water always finds the weak spot. It is patient, persistent, and deeply uninterested in your flooring budget.

Name: Service Lion Plumbing Heating Air Electric

Address: 521 W Briardale Ave, Orange, CA 92865, United States

Phone: (657) 567-7305

Website: <https://callservicelion.com/>

Local Service Information

Service Lion Plumbing Heating Air Electric provides plumbing, drain, heating, air conditioning, and electrical services from its Orange, California location.

The company serves homeowners and properties throughout Orange and communities across Orange County and surrounding areas.

Available services include plumbing repairs, water heater work, drain and sewer services, heating and cooling service, electrical repairs, panels, lighting, outlets, and related home-system work.

Service is available for residential properties as well as light commercial needs described within the company's local service-area information.

The company's website emphasizes locally operated service, coordinated home-system support, and practical scheduling for plumbing, HVAC, and electrical needs.

The matching public business listing shows the Orange location as open 24 hours a day, seven days a week.

For service information or scheduling, call (657) 567-7305 or visit <https://callservicelion.com/>.

The public map listing identifies the business at 521 W Briardale Ave, Orange, CA 92865 and can be used for

location and direction information.

Popular Questions About Service Lion Plumbing Heating Air Electric

What services does Service Lion Plumbing Heating Air Electric provide?

The company provides plumbing, drain and sewer, heating, air conditioning, and electrical services. Its published services include plumbing repair, water heaters, drain clearing, sewer work, HVAC repair and installation, electrical repairs, panels, circuit breakers, lighting, outlets, and related services.

Where is Service Lion Plumbing Heating Air Electric located?

The matching business location is 521 W Briardale Ave, Orange, CA 92865, United States.

What areas does Service Lion Plumbing Heating Air Electric serve?

The company serves Orange County and surrounding communities. Its published service-area information includes Orange, Anaheim, Brea, Yorba Linda, Fullerton, Huntington Beach, Newport Beach, Costa Mesa, Irvine, Lake Forest, and additional nearby cities.

Is Service Lion Plumbing Heating Air Electric open 24 hours?

The matching public business listing shows the location as open 24 hours on Monday through Sunday.

Does Service Lion Plumbing Heating Air Electric work on drains and sewer lines?

Yes. Published services include drain clearing, roofer service, camera inspection, hydro jetting, sewer line repair and installation, water line work, slab leak detection, and trenchless sewer line repair.

Does Service Lion Plumbing Heating Air Electric provide heating and air conditioning service?

Yes. Its published HVAC services include air conditioning repair and installation, heating service, furnace work, heat pumps, air ducts, indoor air quality assessments, and thermostat installation.

Does Service Lion Plumbing Heating Air Electric provide electrical service?

Yes. Published electrical services include repairs and installations, electrical panels, circuit breakers, safety inspections, lighting, outlets and switches, surge protection, generators, and EV charging equipment installation.

How can I contact Service Lion Plumbing Heating Air Electric?

Call [\(657\) 567-7305](tel:6575677305).

Landmarks Near Orange, California

Old Towne Orange Historic District

A central historic district and useful geographic reference point for the Orange community.

Plaza Park

A well-known public gathering point in the center of Old Towne Orange.

Orange Public Library & History Center

A civic landmark serving residents near central Orange.

Hart Park

A major public park and recreation area south of central Orange.

Eisenhower Park

A public park serving neighborhoods in northern Orange.

Santiago Oaks Regional Park

A regional recreation and open-space landmark on the eastern side of Orange.

Irvine Regional Park

A large regional park and recognizable reference point east of the city.

Orange Park Acres

A distinctive residential community and service-area reference point in eastern Orange.

El Modena

An established Orange neighborhood that provides a practical local coverage reference.

Glassell Street

One of the city's principal north-south streets and a useful route through central Orange.

Lincoln Avenue

A major east-west roadway serving northern Orange and nearby communities.

State Route 55

A primary regional freeway connecting Orange with other parts of Orange County.
